British Steel Corporation  
Research Services  
Swinden Laboratories

## ACKNOWLEDGEMENTS

The authors wish to thank the Sections Commercial Division of the British Steel Corporation and the Department of the Environment (through the Fire Research Station) for jointly sponsoring the preparation of this Compendium.

In addition to the fire tests carried out by the British Steel Corporation, Swinden Laboratories, the inclusion of the results from the following organisations is gratefully acknowledged:-

Arbed SA, Belgium  
The Fire Research Station, Borehamwood, UK  
Pell Frischmann & Partners, Manchester, UK

The authors also wish to thank Dr. R. Baker, Director of Research and Development for the British Steel Corporation, for permission to publish this document.

### Consumer Protection Act 1987

The purposes of the Consumer Protection Act 1987 are compatible with BSC's declared objectives of the pursuit of excellence in relation to the quality of its products and its quality systems.

However, arising from the above legislation, British Steel Corporation and its subsidiary companies (BSC) consider it necessary to draw the attention to their customers and users of their products to the following:-

1. BSC has taken every care to ensure that information contained in this document is accurate but regrets that it cannot accept any liability in respect thereof.

## FOREWORD

This compendium of unprotected steel fire test data has been prepared by research staff at the Swinden Laboratories and published on behalf of the UK Department of the Environment Fire Research Station and the British Steel Corporation.

Its main purpose is to provide data for researchers in the study of 'fire resistance of steel structures' particularly in the development of accurate calculation methods, for the determination of high temperature performance and fire resistant design.

It has long been recognised that fire resistance is influenced by section dimensions ( $H/A$ ) and load, and the data published here clearly identifies a third major parameter - the temperature profile through the cross section. It is hoped that the information given on temperature profiles will be used to improve the accuracy of models on the behaviour of steel in fire.

In order to encourage rapid dissemination of information in this field, the publishers invite authors making use of the compendium to send copies of their papers to the Swinden Laboratories address below, so that a reference library covering the behaviour of steel in fire can be evolved for the benefit of other researchers.

Test data on unprotected steelwork from other countries would also be welcomed in order to build up a comprehensive data base and to make available an international compendium in the same format. Blank data sheets, which may be copied, have been included for this purpose and acknowledgement of sources will of course be given.

## PREFACE

This compendium has been prepared covering all the fire tests carried out in the UK, according to BS476:Part 8:1972, on hot rolled structural steel sections in which the members were either completely unprotected, or partially protected by materials used only in the fabric of a structure, such as concrete, brick and blockwork.

The information is presented in the form of a detailed description of the design, preparation and construction for each type of test element and is accompanied in an Appendix, by a series of data sheets. These include information given in much greater detail than that normally reported by the testing stations so that further analysis of the behaviour of the elements under test, can readily be made. In the compendium two further fire tests are reported; one on a square solid steel section carried out to BS476:Part 1:1953 and a single international test on an HD column section following ISO:834.

From the fire test results reported, relationships between heating rate, member size, applied load and fire resistance have been established for several types of load bearing elements based upon analyses carried out by staff at the Swinden Laboratories of the British Steel Corporation.

COMPENDIUM OF UK STANDARD FIRE TEST DATA  
UNPROTECTED STRUCTURAL STEEL - 1

1. INTRODUCTION

One of the aims of the UK Building Regulations is to restrict the spread of fire and minimise the injury and loss of life which could occur should part, or whole of a structure collapse. To this end the 1985 Building Regulations Approved Guidance Document B2/3/4 specifies minimum periods of fire resistance for elements of construction. These range from nil to 4 h depending upon the occupancy and dimensions of the building and reflect the degree of fire safety required for the structure as a whole.

The fire resistance periods stipulated in the Approved Document are those required by parts of a structure (usually as single elements) when subjected to a British Standard 476:Part 8:1972 fire resistance test. However, the substantial costs involved in carrying out fire tests dictate that fire testing programmes are limited and therefore, greater emphasis is now being placed upon the interpolation and extrapolation of results with the aid of computer modelling techniques.

During the last few years, the British Steel Corporation has carried out a considerable number of standard fire tests to examine the performance of structural steelwork without the application of lightweight fire protection products. A range of construction methods has been evaluated reflecting current design practices, as well as alternative forms of construction which are expected to become more widespread.

Some of the information gathered is already being incorporated into British Standards as well as in the preparation of Design Guides for the building industry to permit the safe use of structural steelwork without the need for specialist applied fire protection. However, it is also considered that the fire test data would be of interest to other research, testing and building design organisations internationally as well as in the UK. For this reason, the British Steel Corporation and the Department of the Environment have jointly sponsored the preparation of a compendium of all standard fire tests carried out in the UK, on hot rolled universal sections which were either completely unprotected, or partially protected by materials used only in the fabric of a structure, such as brick, concrete and blockwork.

Many of the fire tests reported in this Compendium form part of ongoing research programmes. Therefore, where appropriate and to assist fire engineers, relationships which have been established between the various parameters are given. However, as further data or alternative analyses become available, these may be modified at some future date. Care must also be taken against using a single test result out of context with other results from tests of a similar nature.

2. BS476:PART 8 FIRE TESTS

The British Standard fire test was first introduced in 1932 and was largely based upon fire testing practices already operating in several other countries, such as the USA. In subsequent years the procedures have been modified and at the present time, the fire resistance of load bearing structural elements is currently assessed in the UK, in accordance with the British Standard 476:Part 8:1972 incorporating Amendments; 1873 (January 1976), 3816 (November 1981) and 4822 (May 1985). However, this standard is currently under review and is expected to be superseded by BS476:Parts 20, 21 and 22.

For a full description of the requirements in the standard, the reader is referred to the standard itself. But briefly, a fire resistance test is carried out on a specimen which as far as possible is representative of the element of construction used in service in terms of its size, materials and workmanship. In the case of structural elements, loads are also applied to simulate the same magnitude and type of stresses generated in practice, although other loadings can be used. The test specimen is heated in a gas fired furnace in which the temperature is controlled to vary with time in

accordance with the ISO recommendations:-

$$T - T_0 = 345 \log_{10} (8t + 1), \text{ } ^\circ\text{C}$$

where  $t$  = time of test, min

$T$  = furnace temperature,  $^\circ\text{C}$ , at time  $t$

$T_0$  = initial furnace temperature,  $^\circ\text{C}$

The heating curve is also graphically illustrated in Fig. 1.

The fire test is terminated either at the request of the sponsor, or when the limiting requirements for maintaining the relevant criteria for stability, integrity and insulation are achieved. At the end of the heating period, the loads are removed on structural elements and then reapplied 24 h later. Should collapse occur at any time during the test procedure, the notional period of stability is taken as 80% of the time to collapse or the duration of heating, if failure occurs during the reload test. In the proposed new fire testing standard the reload test will be optional.

All the tests reported in this Compendium and carried out in the UK were conducted at either the Warrington Research Centre, or at FIRTO - Borehamwood in appropriate gas fired furnaces. Reference is made to the relevant fire test numbers for which certificates have been issued.

Since a range of systems have been evaluated in either a floor, column or wall furnace, the fire tests have been placed in one of three categories and subdivided as follows:-

1. Floor Beam Tests

- (a) Simply supported floor beam
- (b) Simply supported floor beam with composite action between the steel and concrete
- (c) Floor beam with applied rotational end restraining moments
- (d) Floor beam with applied rotational end restraining moments and longitudinal thermal restraint
- (e) Shelf angle floor beam
- (f) 'Slim' floor beam

2. Column Tests

- (a) Column
- (b) Column with blocked in web

3. Wall Tests

- (a) Columns in wall
- (b) Columns or beams in wall with blocked in webs

For each system, a detailed description is provided of the specimen design, preparation and construction with appropriate figures, together with an example of the full loading calculations.

In addition to the fire tests on loaded sections, a series of unloaded, indicative tests have been carried out. Samples of structural sections were placed within the furnaces to obtain further data on the heating rates of the steelwork while the atmosphere followed the ISO heating curve.

All the information derived from the BS476:Part 8 fire tests is presented as a series of data sheets given in Appendix A. These contain data not normally

reported by the test centres and have been presented in such a way that further analyses of the structural behaviour of the elements during the fire tests can be made. The information provided therefore includes the room temperature properties and chemical composition of the member under evaluation, as well as comprehensive temperature profiles of the section at regular intervals during the test.

## 2.1 Steel Quality

Unless specifically stated, all the steel members were manufactured by the British Steel Corporation and supplied to the requirements of BS4360:1979:Grades 43A, 50B and occasionally to 50D. Details of the chemical compositions and minimum tensile properties required by these particular steel qualities are given in Tables 1 and 2.

## 2.2 Dimensions and Section Properties

The relevant nominal dimensions and section properties as specified in BS4:Part 1 and BS4848:Part 4 have been provided for each loaded test element. Where the actual dimensions of the member were measured, these are also included, and for the floor beam tests, the section properties were usually recalculated in order to determine the required loadings.

## 3. OTHER TESTS

In addition to the BS476:Part 8 fire test results, it was considered that for the purpose of research and further structural analyses, data on the high temperature properties of samples removed from the unheated portions of the fire tested members were relevant to this Compendium. This information was derived from a number of anisothermal tensile tests in which a prescribed stress was applied to a specimen at room temperature, which was then heated at a set rate within the range of 2.5-20°C/min. The resulting strain (elastic and plastic) was measured by an extensometer fixed to the specimen. In Appendix B anisothermal high temperature data is therefore presented with cross references to the appropriate members evaluated in the BS476:Part 8 fire test.

## 4. DESIGN, CONSTRUCTION AND TEST PROCEDURES FOR FLOOR BEAMS

The design and preparation of the various types of floor beam assemblies are individually described in the following sections and therefore at this point, a description is only given of the general arrangements and procedures common to all the tests.

All the floor beam tests were carried out at the Warrington Research Centre. For illustrative purposes, Figs. 2(a) and (b) show the furnace used and a floor beam carrying a concrete cover slab on its upper flange being removed after a completed fire test.

The test assembly was mounted in the furnace roof on roller bearing supports set in the walls, to provide an effective span of approximately 4500 mm\* and an exposed length of 4000 mm, as stipulated in the standard. The opening in the furnace roof was completely closed by either a concrete slab cast on top of the upper flange of the beam, or by a series of precast concrete units spanning between the side walls and the floor beam itself.

In addition to the normal requirements of the standard, all the beams were instrumented with 3 mm diameter mineral insulated sheath thermocouples to obtain detailed temperature profiles across the section at various times during the test. Generally the flange temperatures were measured at the 1/4 flange width position (i.e. midway between the flange tip and the centreline of the web), whereas the web temperatures were usually measured at the mid-height of the section. In each case the thermocouple ends were placed in holes predrilled to mid-thickness thereby ensuring bulk steel temperatures were always measured.

---

\* During the period over which fire tests were carried out, repairs and modifications made to the furnace have resulted in small variations in the length of the beam between the two roller bearing supports.

The floor beams were loaded either through the concrete cover slab, or the precast units using hydraulic jacks normally located at four points, viz  $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span. The loads were calculated in order to develop the required bending stress at the centre of the member appropriate to the grade of steel, taking into account the design and dead load of the construction itself\*. For the sizes of sections evaluated, the maximum permissible bending stresses at mid-span according to BS449:1969, are 165 and 230 N/mm<sup>2</sup> for BS4360:1979:Grades 43 and 50 respectively. Where design levels other than the maximum permissible were used, these have been identified as appropriate on the Appendix sheets. It was also assumed that the manner of loading adopted simulated a uniform load distribution along the beam.

An example of the loading calculations is included at the end of the sections dealing with each type of test assembly, and for all the tests described in the Appendix, the key parameters in the calculations are highlighted.

During the test, the furnace temperature was measured and controlled to within the requirements of BS476:Part 8:1972 from six or eight thermocouples symmetrically distributed on both sides of the beam. These were positioned so that their hot junctions were level with the soffit of the beam's flange and 100 mm from the beam.

A potentiometric gauge fixed to the beam at mid-span measured the vertical deflection and within the standard, up to 150 mm (span/30) of movement for a clear span (L) of 4500 mm was permitted. Note however, that in May 1985, Amendment 4822 was introduced which allowed the deflection to proceed beyond L/30 and until whichever was first exceeded of:-

- (a) A deflection of L/20, or
- (b) A rate of deflection described by the equation

$$R = \frac{L^2}{9000d} \quad \text{in mm/min}$$

where L = the clear span, mm

d = the distance from the top of the structural section to the bottom of the design tension zone, mm

Graphs showing deflection v time are included for each test.

Once the heating period was terminated, the loads on the test assembly were removed and then reapplied 24 h later after the system had cooled back to ambient temperature.

#### 4.1 Simply Supported Floor Beams Exposed to Fire on Three Sides

Reference is made to Figs. 3(a) and (b) showing longitudinal and vertical sections of a simply supported floor beam test assembly.

A non-structural grade of concrete (density ~2240 kg/m<sup>3</sup>) was cast onto the upper flange of the test beam to provide a cover slab nominally 650 mm wide x 135 mm thick. This was usually segmented into four units which were held in position by thin gauge steel tangs previously welded to the beam and cast into the concrete. The concrete was allowed to dry out to remove excess moisture prior to testing.

For testing, the beam was positioned in the furnace roof on the roller bearing supports so that the ends were free to move without any restraining action being applied.

---

\* Unless otherwise stated, all the loads were calculated using elastic design in accordance with BS449.

The loads applied to a simply supported floor beam were calculated as follows:-

Steel size : 406 x 178 mm x 60 kg/m universal beam  
Steel quality : BS4360:Grade 43A:1979

Actual dimensions and properties of the floor beam:

Depth of section	(D) = 403 mm
Width of section	(B) = 174 mm
Thickness of flange	(T) = 12.83 mm
Thickness of web	(t) = 8.28 mm
Mass	(m) = 59.8 kg/m
Moment of inertia (x-x)	(I) = 20 706 cm <sup>4</sup>
Distance of neutral axis to the base of beam	(y) = 201.5 mm
Effective span of the beam	(L) = 4500 mm

Maximum allowable bending stress to BS449:Part 2:1969, Table 2

$$f = 165 \text{ N/mm}^2$$

Maximum bending stress required during the test

$$f = 165 \text{ N/mm}^2$$

$$\text{Required bending moment} = \frac{fI}{y} = \frac{wL^2}{8}$$

$$\text{Therefore } w = \frac{8fI}{yL^2} = \text{load per metre run (units converted to kN/m)}$$

$$= 66.984 \text{ kN/m}$$

Concrete cover slab:

Depth	= 125 mm
Width	= 665 mm
Mass	= 1.827 kN/m

Total self weight of beam and concrete cover slab

$$= 2.413 \text{ kN/m}$$

Imposed load to produce required bending stress

$$= 66.984 - 2.413 \text{ kN/m}$$

$$= 64.571 \text{ kN/m}$$

$$\text{Therefore total imposed load} = 290.57 \text{ kN}$$

Using four point loads at  $\frac{1}{8}$ ,  $\frac{3}{8}$ ,  $\frac{5}{8}$  and  $\frac{7}{8}$  span equivalent to  $\frac{wL}{4}$

$$\underline{\text{Loads applied}} = 72.64 \text{ kN}$$

#### 4.2 Simply Supported Floor Beams Exposed to Fire on Three Sides with Composite Action Between the Steel and Concrete Cover Slab

Two tests are reported in which the concrete slab prepared on the upper flange of the beam was cast in reinforced concrete around shear studs welded to the beam. This provided composite action between the steel and concrete.

Reference is made to Figs. 4(a) and (b) showing longitudinal and vertical sections of the test assembly which was designed following the recommendations of CP117:Part 1:1965.

32 shear studs, 75 mm long x 19 mm diameter were welded in two rows along the upper flange of a 254 x 146 mm x 43 kg/m universal beam section to provide the composite action between the steel and concrete. B503 reinforcing mesh was located nominally 35 mm from the upper surface of the flange with any joints overlapping on either side of a shear stud. The size of the mesh measured 200 x 100 mm x a bar diameter of 8 mm, and was placed with the 100 mm bar spacing transverse to the longitudinal axis of the test beam.

The floor slab was cast as two units using concrete supplied to CP110:Part 1:Grade 30:1972 and having a 2 inch slump. Finally an anti-crack chicken wire mesh was incorporated nominally 10 mm below the upper concrete surface.

The design of the shear studs and reinforcement were determined as follows:-

#### Data Used in the Calculations

Concrete slab:

Width	= 635 mm
Depth	= 135 mm
Cube strength	= 30 N/mm <sup>2</sup>

Steel beam:

Depth of section	(D) = 257 mm
Width of section	(B) = 146 mm
Flange thickness	(T) = 12.6 mm
Web thickness	(t) = 7.6 mm
Area of section	(A) = 55.1 cm <sup>2</sup>
Yield stress, min	( $\sigma_y$ ) = 255 N/mm <sup>2</sup>
Moment capacity	= 257.2 kN (factored) (1)
Load on concrete	= 1143 kN

#### Design of Shear Studs

Try 19 mm diameter headed studs 75 mm high  
Design load per stud = 76.2 kN (CP117)  
Number of studs required on each half span  
$$= \frac{1143}{76.2} = 15 \text{ (use 8 pairs)}$$
  
Length of beam = 4535 mm  
Spacing of studs = 283 mm

#### Design of Transverse Reinforcement

CP117 specifies a method of sizing:

For low yield bar  $A_t = 4.71 \text{ cm}^2/\text{m run}$ .

For high yield bar  $A_t = 2.61 \text{ cm}^2/\text{m run}$

Therefore use either:-

low yield bar, 10 mm diameter at 150 mm spacing, or,  
high yield bar, 8 mm diameter at 150 mm spacing.

#### Design of Top Reinforcement

Use A142 mesh or equivalent.

Two identically prepared assemblies were tested. One was loaded as for a simply supported BS4360:Grade 43A beam according to BS449:Part 2:1969, and

ignoring any contribution to the strength and stiffness of the beam by the composite action. The second assembly was loaded taking the composite action into account following CP117:Part 1:1965, and using a load factor of 1.75 in the calculations.

Details of the loading calculations for the two beams are as follows:-

Simply supported floor beam - composite action is ignored.

Section size : 254 x 146 mm x 43 kg/m universal beam  
Steel quality : BS4360:Grade 43A:1979

Actual dimensions and properties of the floor beam:

Depth of section	(D) = 257 mm
Width of section	(B) = 146 mm
Thickness of flange	(T) = 12.45 mm
Thickness of web	(t) = 7.08 mm
Mass	(m) = 41.6 kg/m
Moment of inertia (x-x)	(I) = 6177.7 cm <sup>4</sup>
Distance of neutral axis to the base of beam	(y) = 128.5 mm
Effective span of the beam	(L) = 4530 mm

Maximum allowable bending stress to BS449:Part 2:1969, Table 2

$$f = 165 \text{ N/mm}^2$$

Maximum bending stress required during the test (ignoring any composite action)

$$f = 165 \text{ N/mm}^2$$

Required bending moment

$$= \frac{fI}{y} = \frac{wL^2}{8}$$

Therefore  $w = \frac{8fI}{yL^2}$  = load per metre run (units converted to kN/m)

$$= 30.925 \text{ kN/m}$$

Concrete slab:

Depth	= 130 mm
Width	= 632 mm
Mass	= 1.834 kN/m

Total self weight of beam and concrete slab

$$= 2.242 \text{ kN/m}$$

Imposed load to produce required bending stress

$$= 30.925 - 2.242 \text{ kN/m}$$

$$= 28.683 \text{ kN/m}$$

Therefore total imposed load

$$= 129.93 \text{ kN}$$

Using four point loads at  $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span, equivalent to  $\frac{wL}{4}$

$$\underline{\text{Loads applied}} = 32.47 \text{ kN}$$

The proportion of the applied loads to the working load of the composite beam can be calculated as follows:-

Modular ratio	= 15	
Moment capacity	= 247.2 kN m	
Load in concrete	= 1113 kN	
Section modulus	= 756 cm <sup>3</sup>	
Load factor	= 1.75	
Steel stress at working load	= $\frac{247.2}{1.75} \times \frac{10^3}{756}$	N/mm <sup>2</sup>
	= 187 N/mm <sup>2</sup>	
Applied moment	= $\frac{165}{10^2} \times \frac{6178}{128.5}$	kN m
	= 79.33 kN m	
Steel stress at applied moment	= $\frac{79.33 \times 1.75 \times 187}{247.2}$	N/mm <sup>2</sup>
	= 105 N/mm <sup>2</sup>	

Therefore proportion of full load applied

$$= \frac{105 \text{ N/mm}^2}{187 \text{ N/mm}^2} = 0.56$$

Alternatively, proportion of full stress based upon the beam only

$$= \frac{105 \text{ N/mm}^2}{165 \text{ N/mm}^2} = 0.64$$

Simply supported floor beam - composite action taken into account.

Section size : 254 x 146 mm x 43 kg/m universal beam  
Steel quality : BS4360:Grade 43A:1979.

Actual dimensions and properties of the floor beam:

Depth of section	(D) = 257 mm
Width of section	(B) = 146 mm
Thickness of flange	(T) = 12.6 mm
Thickness of web	(t) = 7.57 mm
Mass	(m) = 41.6 kg/m
Moment of inertia (x-x)	(I) = 6284.7 cm <sup>4</sup>
Distance of neutral axis to the base of beam	(y) = 128.5 mm
Effective span of the beam	(L) = 4530 mm

Concrete slab:-

Width	= 642 mm
Depth	= 130 mm
Mass	= 1.834 kN/m
Moment capacity	= 257.2 kN m (factored) <sup>1</sup>
Required bending moment, $\frac{wL^2}{8}$	= $257.2 \times \frac{1}{1.75}$
	= 146.97 kN m
Therefore load per metre run, w,	= 57.296 kN/m
Total self weight of beam and concrete slab	
	= 2.242 kN/m

Imposed load to produce required bending moment

$$= 57.296 - 2.242 \text{ kN/m}$$

$$= 55.054 \text{ kN/m}$$

Therefore total imposed load = 249.40 kN

Using four point loads at  $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span, equivalent to  $\frac{wL}{4}$

$$\underline{\text{Loads applied}} = 62.36 \text{ kN}$$

#### 4.3 Floor Beams Exposed to Fire on Three Sides with Applied Rotational End Restraining Moments

In Section 4.1, fire tests are described in which floor beams were tested as simply supported members without any restriction on movement being made at the ends. The tests reported in this section show the influence of either variable or constant applied rotational end restraining moments on the fire resistance of floor beams when exposed to fire on three sides. Descriptions of each test assembly are given below together with examples of the loading calculations.

##### 4.3.1 Variable Rotational End Restraint

Figures 5(a), (b) and (c) show longitudinal and vertical sections of the steel beam assembly designed for variable rotational end restraint.

The steel beam provided for a test was extended by welding 0.8 m lengths of the same section size onto each end, using flange and web stiffeners at the joints. In a similar manner described in the preparation of a simply supported floor beam, non-structural concrete (density  $\sim 2240 \text{ kg/m}^3$ ) was cast onto the upper flange to provide a segmented cover slab.

Once the concrete had dried out and the beam instrumented with thermocouples and strain gauges, the test assembly was mounted in the furnace roof on roller bearing supports set 4500 mm apart. The beam projected beyond the furnace at each end by approximately 1 m.

The ends of the beam were bolted to the restraining frame and prior to loading, the fastenings were adjusted for zero restraint. Initially the beam was loaded as for a simply supported member, using jacks applied at four points along the span to generate a maximum tensile stress of  $165 \text{ N/mm}^2$  in the lower flange. From the strain gauge measurements, restraint against rotation occurred about the supports equivalent to a tensile stress of 15% of that for the simply supported condition. Therefore, to restore a maximum bending stress of  $165 \text{ N/mm}^2$  at mid-span, the applied loads were increased by a further 15%.

During the actual fire test, the restraint at the ends of the beam was allowed to change naturally until a deflection of 90 mm (L/50) was achieved at mid-span, at which time the applied loads were reduced to those normally applied for a fully stressed simply supported member. The test continued until the deflection attained 150 mm (L/30).

Details of the loading calculations are as follows:-

Section size : 254 x 146 mm x 43 kg/m universal beam  
Steel quality : BS4360:Grade 43A:1979

Actual dimensions and properties of the floor beam:

Depth of section	(D) = 254 mm
Width of section	(B) = 145 mm
Thickness of flange	(T) = 12.61 mm
Thickness of web	(t) = 7.57 mm
Mass	(m) = 42.4 kg/m
Moment of inertia (x-x)	(I) = 6087.3 cm <sup>3</sup>
Distance of neutral axis to the base of beam	(y) = 127 mm

Effective span of the beam (L) = 4500 mm

Maximum allowable bending stress to BS449:Part 2:1969, Table 2

$$f = 165 \text{ N/mm}^2$$

Required bending stress based upon a simply supported member

$$f = 165 \text{ N/mm}^2$$

$$\text{Required bending moment} = \frac{fI}{y} = \frac{wL^2}{8}$$

$$\text{Therefore } w = \frac{8fI}{yL^2} = \text{load per metre run (units converted to kN/m)}$$

$$= 31.244 \text{ kN/m}$$

Concrete cover slab:

Depth	= 130 mm
Width	= 635 mm
Mass	= 1.814 kN/m

Total self weight of beam and concrete cover slab

$$= 2.230 \text{ kN/m}$$

Imposed load to produce required bending stress

$$= 31.244 - 2.230 \text{ kN/m}$$

$$= 29.014 \text{ kN/m}$$

Therefore total imposed load = 130.56 kN

Using four points loads at  $\frac{1}{8}$ ,  $\frac{3}{8}$ ,  $\frac{5}{8}$  and  $\frac{7}{8}$  span, equivalent to  $\frac{wL}{4}$

$$\text{Loads applied} = 32.64 \text{ kN}$$

When end restraint is applied at each end of a simply supported beam, the load required to produce a working stress of 165 N/mm<sup>2</sup> must be increased to maintain this stress.

Therefore with end restraint at 15% then the new load per metre run

$$w = 31.244 + 0.15 (31.244) \text{ kN/m}$$

$$= 35.934 \text{ kN/m}$$

Imposed load required = 35.934 - 2.230 (beam + concrete) kN/m

$$= 33.704 \text{ kN/m}$$

Therefore total imposed load = 151.67 kN

Using four point loads at  $\frac{1}{8}$ ,  $\frac{3}{8}$ ,  $\frac{5}{8}$  and  $\frac{7}{8}$  span, equivalent to  $\frac{wL}{4}$

$$\underline{\text{Loads applied}} = 37.92 \text{ kN}$$

#### 4.3.2 Constant Rotational End Restraint

Figures 6(a), (b) and (c) show longitudinal and vertical sections of the floor beam assembly designed so that the restraining moments applied at the ends could be held constant during a test.

In these tests, the length of beams supplied enabled approximately 1 m at each

end to project outside the furnace over which the end restraining moments could be applied. A non-structural grade of concrete (density ~2240 kg/m<sup>3</sup>) was cast on to the upper flange over the central 4500 mm portion of the beam, to provide a cover slab as described previously in Section 4.1

Once the concrete had dried out and the beam instrumented, the test assembly was mounted centrally in the furnace roof on roller bearing supports set 4500 mm apart. Each end of the steel beam was held in a cradle arrangement containing a load cell and hydraulic jack. These were fixed to the external restraining frame surrounding the furnace and set at a distance of 0.715 m outside the supports.

Prior to testing, the beam was loaded through the concrete at four points viz, 1/8, 3/8, 5/8 and 7/8 span. The applied loads were calculated for a simply supported beam, i.e. equivalent to maximum bending stresses up to 165 and 230 N/mm<sup>2</sup> for Grades 43 and 50 steels respectively. Depending upon the degree of rotational end restraint required, external loads were also applied through the cradle arrangements to provide the necessary bending moments over the supports.

During the fire tests all the loads were held constant until the vertical deflection at mid-span attained L/30.

Details of the load calculations are as follows:-

Section size : 254 x 146 mm x 43 kg/m universal beam  
Steel quality : BS4360:Grade 43A:1979.

Actual dimensions and properties of the floor beam:

Depth of section	(D) = 256 mm
Width of section	(B) = 147 mm
Thickness of flange	(T) = 12.47 mm
Thickness of web	(t) = 7.05 mm
Mass	(m) = 41.7 kg/m
Moment of inertia (x-x)	(I) = 6165.2 cm <sup>4</sup>
Distance of neutral axis to the base of beam	(y) = 128 mm
Effective span of the beam	(L) = 4530 mm

Maximum allowable bending stress to BS449:Part 2:1969, Table 2

$$f = 165 \text{ N/mm}^2$$

Required bending stress based upon a simply supported member

$$f = 165 \text{ N/mm}^2$$

Required bending moment

$$= \frac{fI}{y} = \frac{wL^2}{8}$$

Therefore  $w = \frac{8fI}{yL^2}$  = load per metre run (units converted to kN/m)

$$= 30.983 \text{ kN/m}$$

Concrete cover slab:

Depth	= 130 mm
Width	= 630 mm
Mass	= 1.800 kN/m

Total self weight of beam and concrete cover slab

$$= 2.209 \text{ kN/m}$$

Imposed load to produce required bending stress

$$= 30.983 - 2.209 \text{ kN/m}$$

$$= 28.774 \text{ KN/m}$$

Therefore total imposed load = 130.35 kN

Using four point loads at  $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span, equivalent to  $\frac{wL}{4}$

$$\underline{\text{Loads applied}} = 32.59 \text{ kN}$$

Rotational end restraint:

Central bending moment of a simply supported beam

$$\frac{wL^2}{8} = 73.809 \text{ kN m}$$

where  $w = 30.983 \text{ kN m}$

$$L = 4.530 \text{ m}$$

Rotational end restraint required  $\cong$  30% of of the bending moment of a simply supported beam (without end restraint).

This is achieved by applying loads at the ends of the beam to generate end moments over the roller bearing supports equivalent to 30% of the central moment.

Therefore end moments required = 30% of 73.809 kN m

$$= 22.143 \text{ kN m}$$

Distance between the roller bearing supports and applied end loads

$$= 0.715 \text{ m}$$

Therefore applied end loads = 30.97 kN

#### 4.4 Floor Beams Exposed to Fire on Three Sides with Applied Rotational End Restraining Moments and Longitudinal Thermal Restraint

In Section 4.3.2 fire tests on floor beams are described in which additional loads were applied outside the furnace on extended members to provide rotational end restraining moments over the supports. This approach has been extended so that restraint was provided by restricting longitudinal thermal expansion as well as applying the end moments over the supports.

In addition to the furnace frame providing a reaction for the end moments, a second steel 'picture frame' was constructed around the furnace roof, level with the test beam as shown schematically in Fig. 7(a). This was fabricated by bolting 254 x 254 mm x 73 kg/m universal column sections to 914 x 305 mm x 224 kg/m universal beam sections.

A segmented non-structural concrete cover slab (density  $\sim 2240 \text{ kg/m}^3$ ) was cast onto the upper flange along the beam's 4500 mm long central portion and allowed to dry out prior to testing. Apart from instrumenting the beam with thermocouples, strain gauges were also attached to those parts located outside the furnace. As before, the test assembly was mounted in the furnace roof on roller bearing supports set nominally 4500 mm apart and with the ends of the beam positioned inside the thermal restraining frame. Shims were used to take up any clearance gaps. Between the furnace supports and the thermal restraining frame each end of the beam was also held in a cradle arrangement housing a load cell and hydraulic jack, see Fig. 7(b). This was fixed to the separate restraining frame surrounding the furnace and as described in the

previous section, was used to apply and maintain constant rotational end restraining moments over the supports.

Prior to testing, the beam was loaded through the concrete at four points, viz,  $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span. The applied loads were calculated for a simply supported beam, i.e. equivalent to maximum bending stresses up to 165 and 230 N/mm<sup>2</sup> for Grades 43 and 50 steels respectively. Depending upon the degree of rotational end restraint required, external loads were also applied through the cradle arrangements to provide the necessary bending moments over the supports.

During the fire test all the loads were held constant until the heating period was terminated, when the vertical deflection at mid-span attained L/30. The load calculations were identical to those already described in Section 4.3.2 for a floor beam with applied constant rotational end restraining moments.

#### 4.5 Simply Supported Shelf Angle Floor Beams

Reference is made to Figs. 8(a) and (b) showing the plan view and vertical cross section of a shelf angle floor beam test assembly.

A shelf angle floor beam was fabricated by bolting 125 x 75 mm x 12 mm thick steel angles through the shorter leg, onto each side of the web of the beam. Grade 8.8, M20 size bolts were generally used throughout and these were spaced at 600 mm centres. The position of the angles with respect to the beams upper flange was governed by the thickness of the precast units to be placed on the angles, with an additional clearance gap of nominally 10 mm being allowed between the underside of the top flange and the unexposed surface of the concrete. Once fabricated, the beam and angles were instrumented with thermocouples to provide detailed heating data during the test.

The beam assembly was mounted in the furnace roof on roller bearing supports set nominally 4500 mm apart. A series of 16 (8 each side) reinforced precast concrete floor units, nominally 1550 mm long x 550 mm wide, were positioned to span between the furnace side walls and the shelf angle floor beam. Each unit utilised a minimum 75 mm load bearing length on the shelf angles thereby leaving a gap of approximately 50 mm between the ends of the units and the section's web. A gap of 12 mm was also left between the units and the end walls to allow uninterrupted movement for when the beam deflected vertically during the test. Ceramic fibre was used to cover the gaps to prevent undue heat loss.

The precast reinforced units used in these tests were manufactured either as a uniform 200 mm deep section, or a 150 mm deep section with a 50 mm x 300 mm long taper at one end which fitted into the steel beam. Design details for the two units are shown in Figs. 9(a) and (b). Note that given in the notes for each of the relevant data sheets is the height of the exposed steel measured from the underside of the beams lower flange to the underside of the concrete floor units.

Normal site practice entails laying a floor screed over the shelf angle floor and therefore to simulate similar thermal characteristics, dry sand was used to fill the 50 mm gap between the slab ends and the beam, and to provide a 25 mm cover over the upper flange.

Unlike the floor beam tests described previously, a shelf angle floor beam was loaded through the concrete units 0.5 m from its centreline. This was achieved by applying loads using hydraulic jacks at eight points ( $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span on each side) onto 1 m lengths of 152 x 152 mm universal column section to act as load spreaders.

The fire test procedures were carried out in a similar manner to other floor beam tests. However, at the time the tests were conducted, it was the intention to incorporate Amendment 4822 (May 1985) into BS476:Part 8 and therefore, several tests were allowed to proceed until the vertical deflection at mid-span attained L/20.

Details of the load calculations are as follows in which reference is made to Fig. 10:-

Section Size

Steel Quality

406 x 178 mm x 54 kg/m universal beam	BS4360:Grade 43A:1979
125 x 75 x 12 mm x 17.8 kg/m angle	BS4360:Grade 50B:1979

Nominal dimensions and properties of the floor beam:

Depth of section	(D) = 402.6 mm
Width of section	(B) = 177.6 mm
Thickness of flange	(T) = 10.9 mm
Thickness of web	(t) = 7.6 mm
Mass	(m) = 54 kg/m
Moment of inertia (x-x)	(I) = 18626 cm <sup>4</sup>
Distance of neutral axis to the base of beam	(y) = 201.3 mm
Effective span of beam	(L) = 4500 mm

Maximum allowable bending stress to BS449:Part 2:1969, Table 2

$$f = 165 \text{ N/mm}^2$$

Required bending stress based upon a simply supported member

$$f = 165 \text{ N/mm}^2$$

Therefore safe working load,  $wL$ , =  $\frac{8fI}{yL}$

$$= 271.4 \text{ kN}$$

Note: Any contribution made by the angles towards the moment capacity of the beam is ignored.

Operating load required = 271.4 kN

Self weight of beam and sand = ~5.5 kN

Therefore total force required to act through the angles

$$= 265.9 \text{ kN}$$

Forced required to act through each angle

$$= 133.0 \text{ kN}$$

Self weight of concrete units and load spreaders

$$= ~72 \text{ kN}$$

Reaction on each angle =  $\frac{72}{2} \times \frac{1}{2} = 18 \text{ kN}$

Imposed force required on each angle to produce working stress in test beam

$$= 115.0 \text{ kN}$$

Load required on each side of the test beam 0.5 m from its centreline (see Fig. 10)

$$= 115 \times \frac{1.460}{1.052} \text{ kN}$$

$$= 159.6 \text{ kN}$$

Load required by each jack = 39.90 kN

#### 4.6 Simply Supported 'Slim' Floor Beams

Figures 11(a) and (b) show the plan view and vertical cross section of a simply supported 'slim floor' beam test assembly.

A 'slim' floor was prepared by mounting a 5 m long 254 x 254 mm universal column section instrumented with thermocouples in the furnace roof on roller bearing supports set 4500 mm apart. Using a similar arrangement to a shelf angle floor beam, two rows of precast, concrete floor units were placed to span between the furnace walls and the upper face of the column's lower flange. The concrete units were supplied either by Richard Lees Ltd. as standard prestressed 'Spiroll' hollow units, 1550 mm long x 550-590 mm wide x 200 mm deep, or, as solid reinforced concrete units, 1550 mm long x 550 mm wide x 200 mm deep. Their design details are given in Figs. 12(a) and (b) which shows one end of the hollow units having a 100 mm x 250 mm long taper. This end was located in the steel column between the flanges.

In constructing the 'slim' floor, the concrete units utilised a minimum load bearing length of 75 mm on the columns' lower flange which left a gap of approximately 48 mm between the tapered edge and the section's web. A 12 mm gap was also left at each end of the column between the concrete units and the furnace walls to allow uninterrupted movement as the member deflected vertically during the test. This was covered with ceramic fibre to prevent undue heat loss.

Finally to simulate the thermal characteristics of a floor screed, the construction was completed by placing sand in the void between the floor units and column section as well as over the upper flange of the section itself.

A 'slim' floor was loaded in an identical manner to a shelf angle floor in which eight hydraulic jacks (four on each side) applied loads at  $1/8$ ,  $3/8$ ,  $5/8$  and  $7/8$  span onto 1 m long load spreaders. These were set 0.5 m from the centreline of the beam.

The loading applied to a slim floor test assembly was calculated as follows:- Initially the hydraulic loads required to generate near maximum permissible bending stresses in the member's lower flange were estimated. These were then used to accurately calculate the total stresses in the system by specifically defining the longitudinal bending stresses and secondary stresses acting in the lower flange.

Section size : 254 x 254 mm x 89 kg/m universal column  
Steel quality : BS4360:Grade 43A:1979

Nominal dimensions and properties of the floor beam:

Depth of section	(D) = 260.4 mm
Width of section	(B) = 255.9 mm
Thickness of flange	(T) = 17.3 mm
Thickness of web	(t) = 10.5 mm
Mass	(m) = 89 kg/m
Moment of inertia (x-x)	(I) = 14307 cm <sup>4</sup>
Distance of neutral axis to the base of beam	(y) = 130.2 mm
Effective span of beam	(L) = 4500 mm

Maximum allowable bending stress to BS449:Part 2:1969, Table 2

$$f = 165 \text{ N/mm}^2$$

Required bending stress based upon a simply supported member

$$f = 165 \text{ N/mm}^2$$

$$\text{Therefore safe working load, } wL, = \frac{8fI}{yL}$$

$$= 322.3 \text{ kN}$$

Operating load required = 322.3 kN

Self weight of column and sand = 5.5 kN

Therefore total force required to act through the lower flanges  
= 316.8 kN

Force required to act through each flange  
= 158.4 kN

Self weight of concrete and load spreaders  
= 72 kN

Reaction on each flange =  $\frac{72}{2} \times \frac{1}{2}$  = 18 kN

Imposed force required on each flange to produce working stress in member  
= 140.4 kN

Estimate of loads required to generate near maximum working stresses in the 'slim' floor member taking into account local bending and shear stresses in the lower flange = 171 kN (applied on either side at a distance of 0.5 m from its centreline).

Load required by each jack = 42.75 kN

Calculation of actual stress produced:-

Force on each flange due to imposed load (see Fig. 13)

$$= 171 \times \frac{1.050}{1.461} = 122.9 \text{ kN}$$

Force on each flange due to dead load (concrete + load spreaders)  
= 18 kN

The manner in which the concrete units rest on the lower flanges can be considered either, as a uniformly distributed load (UDL) over the bearing length, or, as a point load of contact. Both cases are analysed:

(a) UDL Case

Compressive bending stress/flange due to imposed load  $\left(\frac{M}{Z}\right)$

$$= \frac{122.9 \times 72 \times 6 \times 1000}{4.5 \times 1000 \times (17.3)^2} = -39.4 \text{ N/mm}^2$$

Compressive bending stress/flange due to dead load  $\left(\frac{M}{Z}\right)$

$$= \frac{18 \times 72 \times 6 \times 1000}{4.5 \times 1000 \times (17.3)^2} = -5.8 \text{ N/mm}^2$$

$$\text{Total } (\sigma_2) = -45.2 \text{ N/mm}^2$$

Longitudinal stress at mid-span  $(\sigma_1) = \frac{wYL^2}{8I}$

$$= \frac{\left\{ \frac{287.3 \times 1000}{4500} \right\} \times 130.2 \times (4500)^2}{8 \times 14 \times 307 \times 10^4}$$

$$= 147.1 \text{ N/mm}^2$$

Therefore combined stress on lower flange

$$\sigma = \frac{1}{\sqrt{2}} [(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2]^{\frac{1}{2}}$$

$$= 0.707 [(192.3)^2 + (45.2)^2 + (147.1)^2]^{\frac{1}{2}}$$

$$= \underline{174.1 \text{ N/mm}^2}$$

(b) Point Load Case

Compressive bending stress/flange due to imposed load  $\left(\frac{M}{Z}\right)$

$$= -18.6 \text{ N/mm}^2$$

Compressive bending stress/flange due to dead load  $\left(\frac{M}{Z}\right)$

$$= -2.7 \text{ N/mm}^2$$

$$\text{Total } (\sigma_2) = -21.3 \text{ N/mm}^2$$

Longitudinal stress at mid-span ( $\sigma_1$ )

$$= 147.1 \text{ N/mm}^2$$

Therefore combined stress on lower flange

$$\sigma = \frac{1}{\sqrt{2}} [(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2]^{\frac{1}{2}}$$

$$= 0.707 [(168.4)^2 + (21.3)^2 + (147.1)^2]^{\frac{1}{2}}$$

$$= \underline{158.8 \text{ N/mm}^2}$$

From the above analyses, the loads applied to the floor assembly produced a maximum stress in the member's lower flange of either 174.1 N/mm<sup>2</sup> or 158.8 N/mm<sup>2</sup> depending upon the assumed area of contact between the concrete units and the steel. These represent 105.5% and 96.2% respectively of the maximum permissible load according to BS449:1969.

## 5. DESIGN, CONSTRUCTION AND TEST PROCEDURES FOR COLUMNS

The design and construction of column test assemblies are given below and briefly cover the general arrangement and procedures common to all the tests. However, as an exception, one international test sponsored by Arbed SA in Belgium on a particular heavy HD column section has been included.

All the UK column tests reported were conducted at FIRTO, Borehamwood. For illustrative purposes, Figs. 14(a) and (b) show a bare column positioned in the furnace prior to testing and a similar column section but with its web blocked in, after a completed test.

A test specimen was prepared by welding steel plates, 406 x 406 mm x 19 mm thick onto each end of a 3.64 m long column section. This was mounted vertically on a similar steel plate which formed the base of the loading frame. Concrete caps were cast around both ends to leave a 3.00 m length of section

exposed to the fire. The caps were used solely as a means of closing the furnace ends and were not reinforced.

In addition to the requirements of the testing station, the column was instrumented with 3 mm diameter mineral insulated sheath thermocouples to obtain detailed temperature profiles across the section at various times during the test. The locations and temperature data recorded from the thermocouples are given for each individual test in Appendix A.

Generally, the flange temperatures were measured at the  $1/4$  width position (i.e., midway between the flange tip and the centreline of the web), whereas the web temperatures were usually measured at the centre position between the two flanges. In each case the thermocouple ends were placed in holes predrilled to mid-thickness thereby ensuring bulk steel temperatures were always measured.

A split vertical furnace was positioned around the column and its temperature rise measured and controlled to follow the ISO heating curve using six thermocouples. These were located symmetrically inside the furnace with their hot junctions located 100 mm from the column. During the test the vertical deflection of the column was measured by a displacement transducer.

Prior to lighting the furnace, a column was loaded by hydraulic jacks for which the applied loads were calculated in accordance with BS449:Part 2:1969. Since the column was effectively held in position and restrained in direction by the loading system end fixity was assumed, and therefore, in calculating the axial loadings an effective length of  $0.7L$  was adopted.

Within BS476:Part 8:1972, the fire resistance of a column is judged by its compliance with the criterion for stability only, and therefore a fire test is terminated at any time up to the point when the axial load can no longer be maintained. At the end of the heating period, the load was removed and then reapplied 24 h later when the test specimen had returned back to ambient temperature.

### 5.1 Column Exposed on Four Sides (UK Tests)

Figure 15 shows the test arrangement for a steel column exposed to fire on four sides. The test procedures have already been described in Section 5 and therefore the applied loads were calculated as follows:

Section size : 203 x 203 mm x 52 kg/m universal column  
Steel quality : BS4360:Grade 43A:1979

Dimensions and properties of the column:

Depth of section	(D)	=	204.5 mm
Width of section	(B)	=	204.0 mm
Thickness of flange	(T)	=	12.5 mm
Thickness of web	(t)	=	8.0 mm
Radius of gyration	( $r_{yy}$ )	=	5.16 cm
Area of cross section	(A)	=	66.4 cm <sup>2</sup>
Exposed column length	(L)	=	300 cm
Effective column length	(l)	=	$0.7 \times L = 210$ cm
Slenderness ratio	( $l/r_{yy}$ )	=	$\frac{210}{5.16} = 40.69$ (41 assumed)

Maximum allowable axial stress to BS449:Part 2:1969, Table 17(a)

$$P_c = 138 \text{ N/mm}^2$$

Therefore maximum permissible load =  $P_c \times A$  (units converted to kN)

$$= 916 \text{ kN}$$

Load applied = 550 kN (60% of maximum permissible load)

### 5.1.1 Columns Exposed on Four Sides (International Test)

The result of one test conducted at the fire station at Ghent University, Belgium, and sponsored by Arbed SA is reported. This was carried out on a particularly heavy 400 x 400 x 744 kg/m HD section following the test procedures given in ISO:834.

One notable difference of this test compared to those conducted in the UK, is the testing of columns in pairs with the loading applied eccentrically through the flanges, see Fig. 16.

### 5.2 Columns with Blocked in Webs Exposed to Fire on Four Sides

A description has already been given of the construction and test procedures for an unprotected steel column exposed on four sides, and therefore the following information principally covers details concerning the protection of the web of the section by lightweight aerated pulverised fuel ash (pfa) blockwork.

Figures 17(a) and (b) show the general arrangement for a steel column exposed on four sides with its web protected by blockwork.

Blocks of lightweight aerated pfa were built between the column flanges to protect the web over its entire exposed length. Depending upon the manufacturer, the blocks were supplied to the following dimensions; 440 x 290 x 100 mm or 450 x 225 x 100 mm. These were cut to fit into the web with a standard mortar joint. No mechanical fixing was used to tie the blockwork into the steel. A 13 mm gap lightly filled with ceramic fibre, was left at the top of the construction between the blockwork and the concrete cap to ensure that the former remained non-load bearing during the test.

Prior to testing, time was given for the mortar to dry and for the blockwork to condition itself to the environmental conditions inside the testing station. On the day of the test, both the oven dry density and moisture content from a sample of blockwork were determined.

The axial loads applied to a column were calculated as follows:

Section size : 203 x 203 mm x 46 kg/m universal column  
Steel quality : BS4360:Grade 43A:1979

Dimensions and properties of the column:

Depth of section	(D)	=	203.0 mm
Width of section	(B)	=	202.0 mm
Thickness of flange	(T)	=	10.5 mm
Thickness of web	(t)	=	7.0 mm
Radius of gyration	( $r_{yy}$ )	=	5.11 cm
Area of cross section	(A)	=	58.8 cm <sup>2</sup>
Exposed column length	(L)	=	300 mm
Effective column length	(l)	=	0.7 x L = 210 cm
Slenderness ratio	( $l/r_{yy}$ )	=	$\frac{210}{5.11} = 41.09$

Maximum allowable axial stress to BS449:Part 2:1969, Table 17(a)  
(for the steel column only)  $P_c = 138 \text{ N/mm}^2$

Therefore maximum permissible load =  $p_c \times A$  (converting units to kN)  
= 811 kN

Load applied = 811 kN

6. DESIGN, CONSTRUCTION AND TEST PROCEDURES FOR COLUMNS AND BEAMS BUILT INTO CAVITY WALLS

The following section covers fire resistance tests on vertical separating elements carried out at FIRTO, Borehamwood. These consisted of universal columns or beams built into a cavity wall construction so that either one flange or a flange + part of the web from each section, was exposed to the fire.

Figure 18 schematically illustrates the type of construction under evaluation and in Figs. 19(a)-(e), photographs show the steelwork during fabrication as well as the exposed and unexposed wall surfaces before and after a test.

Details covering the two systems are given individually and therefore the following description is a summary of the test procedures common to all the wall tests.

A wall structure measuring at least 2.5 m high x 2.5 m long was constructed on a concrete base which was embedded in a loading frame placed in front of the furnace. In constructing a wall, care was taken to prevent any restraint occurring around the edges by leaving clearance gaps lightly packed with mineral fibre. The ISO heating curve was monitored and controlled via sixteen thermocouples positioned symmetrically in the furnace. These were located so that their hot junctions were situated 100 mm from the exposed wall face. In addition, heat transmitted through the wall was measured by seven thermocouples fixed to the unexposed surface on to copper discs which were then covered by non-asbestos mill board pads.

Any horizontal movement perpendicular to the wall structure occurring during a test, was measured at mid-height. This was achieved by two displacement transducers connected by wire to steel rods protruding through the brick wall and welded to the columns. The mean longitudinal extension in the wall was also measured by displacement transducers fitted at each end of the cross-head.

In addition to the thermocouples placed around the wall assembly by the testing station, 3 mm diameter mineral insulated sheath thermocouples were embedded into the steel columns to obtain temperature profiles across the sections at various height positions. These are identified on each of the Appendix sheets. Generally, the flange temperatures were measured at the  $\frac{1}{4}$  width position (i.e. mid-way between the flange tip and the centreline of the web), whereas the temperatures in the web were measured at various locations depending on the construction. However, in each case the thermocouple ends were placed in holes predrilled to mid-thickness thereby ensuring bulk steel temperatures were always measured.

The wall structure was loaded through the end plate welded to the steel sections and maintained for the duration of the test. Once the heating period was terminated, the loads were removed and then reapplied 24 h later when the test assembly had cooled back to ambient temperature.

The fire resistance of a load bearing separating element is determined from when the test is terminated or when failure occurs under any one of the following criteria; stability, integrity and insulation.

6.1 Columns in Walls

Reference is made to Figs. 20(a)-(c) showing the general arrangements for the wall construction.

End plates, 406 mm square x 20 mm thick were welded to a pair of 2.92 m long 203 x 203 mm x 52 kg/m universal column sections. These in turn were welded or bolted to two steel plates 3050 x 580 mm x 20 mm thick to form a frame with the columns at 1.02 m centres, and positioned equidistant from the centre width of the assembly.

A concrete slab, 2050 x 580 mm x 250 mm thick was cast on top of the bottom steel plate around the columns bases. This slab had a nominal density of 2210 kg/m<sup>3</sup> and apart from an anti-cracking mesh, did not contain any reinforcement. A 3.08 m long x 2.68 m high cavity wall with an overall thickness of 250 mm was

built up from the concrete base. This comprised a 102 mm thick fletton brick wall located 12 mm from one of the outside faces of the steel columns, a 50 mm cavity and a second wall 100 mm thick built using aerated pulverised fuel ash concrete blocks which abutted up to the columns' webs. Butterfly wire wall ties (3.2 mm diameter) held the two wall leaves together and six were evenly spaced on every sixth cours of fletton bricks. Throughout the construction a 1:6 ordinary mortar mix with an added plasticiser was used.

Between the top steel plate and the wall construction, a 30 mm gap was left to ensure that the load was only carried by the columns. Gaps approximately 40 mm wide were also left between the wall's vertical edges and the loading rig to prevent any restraining action. All the gaps were lightly filled with mineral wall. On the blockwork (fire) side, mineral fibre was fitted around the top of the specimen to protect the upper steel plate. This reduced the height of the exposed wall structure to 2.5 m.

Prior to testing, the wall structure was given a conditioning period to remove excess moisture from the mortar and blockwork.

The loads placed upon the wall constructions were calculated as follows:

Section size : 203 x 203 mm x 52 kg/m universal column  
 Steel quality : BS460:Grade 43A:1979

Dimensions and properties of the columns:

Depth of section	(D)	= 206.2 mm
Width of section	(B)	= 203.9 mm
Thickness of flange	(T)	= 12.5 mm
Thickness of web	(t)	= 8.0 mm
Radius of gyration	( $r_{xx}$ )	= 8.90 mm
Radius of gyration	( $r_{yy}$ )	= 5.16 cm
Area of cross section	(A)	= 66.4 cm <sup>2</sup>

Column length	(L)	= 300 cm (ignoring the concrete base)
---------------	-----	---------------------------------------

The columns are regarded as being effectively held in position at both ends and restrained in direction at one end.

Therefore effective length (l) = 0.85 x L = 255 cm

Slenderness ratio ( $l/r_{xx}$ ) = 28.65

Maximum allowable axial stress to BS449:Part 2:1969, Table 17(a)

$$P_c = 143.5 \text{ N/mm}^2$$

Therefore maximum permissible load per column

$$= P_c \times A \text{ (converting units to kN)}$$

$$= 953 \text{ kN}$$

Total load applied = 953 kN (50% of maximum permissible load)

## 6.2 Columns and Beams in Walls with Blocked in Webs

Reference is made to Figs. 21(a)-(c) showing the general arrangement for the wall construction.

End plates 406 mm square x 20 mm thick were welded to a pair of 2.92 m long universal column or beam sections. These in turn were welded to two steel plates 3050 x 580 mm x 20 mm thick to form a frame with the members at 1.02 m centres, and positioned equidistant from the centre width of the assembly.

A concrete slab, 3050 x 580 mm x 250 mm thick was cast on top of the bottom steel plate around the members bases. The slab had a nominal density of 2210 kg/m<sup>3</sup> and apart from an anti-cracking mesh did not contain any reinforcement.

A cavity wall 3.08 m long x 2.68 m high with an overall thickness of 250 mm was built up from the concrete base. This comprised, a 102 mm thick fletton brick wall positioned approximately 25 mm from one of each of the column flanges, a 50 mm cavity and a second wall 100 mm thick built from aerated pfa concrete blocks. The blocks abutted up to the webs of the sections and a 12 mm mortar joint was also made between the blockwork and the inside face of the back (cavity) flanges. Butterfly wire wall ties (3.2 mm diameter) held the two wall leaves together and six were evenly spaced on every sixth course of fletton bricks. The space between the outer face of the blockwork wall and the exposed flanges was completely filled with blockwork and keyed into the wall to leave only the outer faces and edges exposed to fire. Throughout the construction a 1:6 ordinary mortar mix with an added plasticiser was used.

The remainder of the detailing was identical to that already described in Section 6.1.

The loadings placed upon the wall constructions were calculated as shown below. However, following the tests on columns in walls, described in Section 6.1, examination of the test behaviour indicated that alternative values regarding the effective length were more appropriate in the calculation procedures.

Section size : 203 x 203 mm x 52 kg/m universal column  
Steel quality : BS4360:Grade 43A:1979

Dimensions and properties of the column:

Depth of section	(D)	= 206.2 mm
Width of section	(B)	= 203.9 mm
Thickness of flange	(T)	= 8.0 mm
Thickness of web	(t)	= 12.5 mm
Radius of gyration	( $r_{xx}$ )	= 8.90 cm
Radius of gyration	( $r_{yy}$ )	= 5.16 cm
Area of cross section	(A)	= 66.4 cm <sup>2</sup>
Column height	(L)	= 300 cm (ignoring the concrete base)

Examination of the test behaviour suggests that:-

for the x-x axis the effective length factor = 1.0 to 1.2 (estimate)  
for the y-y axis the effective length factor = 1.0.

Therefore effective length,  $l_{xx}$ , =  $L \times 1.2 = 360$  cm  
and effective length,  $l_{yy}$ , =  $L \times 1.0 = 300$  cm

Slenderness ratio ( $l/r_{xx}$ ) = 40.45

Slenderness ratio ( $l/r_{yy}$ ) = 58.14

Hence y-y axis dominates collapse and the maximum allowable axial stress to BS449:Part 2:1969, Table 17(a).

$$p_c = 127 \text{ N/mm}^2 \text{ (for } l/r = 58)$$

Therefore maximum permissible load per column

$$= p_c \times A \text{ (converting units to kN)}$$

$$= 843.3 \text{ kN}$$

$$\underline{\text{Total load applied}} = 1686.6 \text{ kN}$$

## 7. INDICATIVE TESTS

Indicative tests are reported on full size universal sections when heated in a column or floor furnace without the application of any loading. Further data is also given on short lengths of steel sections approximately 1 m long positioned in the floor furnace to simulate the effect of either heating a

floor beam exposed on three sides, or a column or beam exposed on four sides. For the former, the beams were bolted to the underside of the roof and projected at an angle towards the furnace centre from the corners, see Fig. 22, whereas the columns were generally placed upright along the furnace centreline on plinths, see Fig. 23. In addition, heating data were obtained for a universal beam section built into the wall of the 1 m cube indicative furnace at the Warrington Research Centre to simulate the conditions of a perimeter beam exposed only on one side, see Figs. 24(a) and (b).

In Appendix A data sheets are presented showing the type of test with detailed heating data across the profile of the section as the furnace atmosphere followed the ISO heating curve.

## 8. DATA ANALYSIS

Analysis of the data by staff of Swinden Laboratories of the British Steel Corporation has established several relationships between heating rate, member size, applied load and fire resistance for several types of load bearing elements. These are highlighted as follows:-

### 8.1 Section Factor ( $H_p/A$ ) and Heating Rates for Unprotected Floor Beams and Columns

The  $H_p/A$  concept is widely used by fire engineers and fire protection designers to relate the size and shape of a member with its heating rate in both natural and standard fire test conditions.  $H_p$  is the heated perimeter of the member (m) and A is its cross section area ( $m^2$ ). Values of  $H_p/A$  for hot rolled universal beams and columns manufactured by BSC are given in Table 3. Therefore for a particular element of construction a section rolled with thick flanges and web will under the same fire conditions, heat up more slowly than a light section which has relatively thin flanges and web.

While the relationships between heating and  $H_p/A$  are not exact due to, for example, members having dissimilar radiation view factors but identical values of  $H_p/A$ , Figs. 25 and 26 present heating curves for a range of section factors covering universal beam and column sizes currently manufactured by BSC. In Fig. 25, the heating curves relate to the lower flanges of floor beams exposed to fire on three sides, whereas those given for Fig. 26 are the mean between the two flanges and web when the columns are fully exposed to fire on four sides.

### 8.2 Fire Resistance of Simply Supported Floor Beams

The fire resistance of simply supported floor beams covering the entire range of BSC sections available cannot be evaluated in existing test facilities. They can however, be calculated using finite element computer models and checked against limited experimental data. In view of the limitations in terms of span, size and loading of steel members in the fire test furnaces, data obtained from the tests reported have been used in conjunction with the computer model, FASBUS II, to extrapolate beyond the scope of full scale testing.

FASBUS II is a finite element model developed by Messrs. Bressler and Iding of Weiss, Janney Elstner and Associates for predicting the behaviour of floors in fire by combining a thermal analysis with a structural analysis.

#### 8.2.1 Influence of Section Factor ( $H_p/A$ ) on Fire Resistance

Figure 27, based upon the FASBUS II model, illustrates the influence of  $H_p/A$  on the fire resistance of bare steel floor beams when tested at full design loading (to BS449:1969) in a 4.5 m span floor furnace. The fire resistance period is the time taken for the vertical deflection at mid-span to attain  $L/30$ . In addition it is worth noting that since high rates of deflection are achieved towards the latter stages of the test, the fire resistance times predicted would not be altered when evaluated in consideration of Amendment 4822 (May 1985) to BS476:Part 8:1972. This is due to the limiting rate of deflection,  $L^2/9000 d$ , being exceeded before the mid-span vertical deflection attains  $L/30$ .

### 8.2.2 Influence of Design Stress on Limiting (L/30) Temperature

Data from the fire tests carried out on fully stressed (to BS449:1969) simply supported floor beams, show that the temperatures attained in the lower flange at the limit of deflection, fall within the range of 634-683°C with a mean of 660°C. These high temperatures, in excess of the traditionally quoted 550°C, are due, at least in part, to the temperature gradient experienced down through the section where the upper flange temperatures were only about 440°C at the limiting deflection. Again using the FASBUS II model, Fig. 28, illustrates the influence of design stress on the temperature attained at L/30 in the lower flanges of 254 x 146 mm x 43 kg/m universal beams tested in the floor furnace. Under BS449:1969 a tensile stress of 165 N/mm<sup>2</sup> in the lower flange of a floor beam corresponds to the maximum permissible design load for a Grade 43A steel section. A beam under a reduced design stress of 83 N/mm<sup>2</sup> would be stable up to a limiting temperature of approximately 750°C.

### 8.3 Influence of Composite Action on Fire Resistance

Two tests were carried out to examine the effect on fire resistance of providing composite action between a reinforced concrete floor slab and the steel beam. When a 254 x 146 mm x 43 kg/m universal beam section is loaded without the increase in moment capacity of the assembly being taken into account, i.e. the beam is not at full working load, a marked improvement in fire resistance is achieved. In contrast, by loading a composite beam assembly to maximise the permitted available moment capacity, then a similar fire resistance to that of a simply supported beam with a non-structural, non-composite segmented cover slab is obtained.

### 8.4 Influence of Rotational End Restraining Moments and Thermal Restraint on The Fire Resistance of Floor Beams

The test data show that a marked improvement in the fire resistance is obtained when end restraining moments are applied to floor beams. These results have been used to obtain an approximate relationship between  $H_p/A$  and the % rotational end restraint necessary to achieve 30 min fire resistance for Grade 43A and 50B structural sections. This is shown in Fig. 29 and applies to beams loaded to generate a maximum tensile stress of 165 N/mm<sup>2</sup> in the lower flange (irrespective of Grade) for a simply supported end condition. Needless to say a Grade 50B steel section would be understressed.

From the tests using the thermal restraining frame, restraint on expansion was found not to be detrimental to the fire resistance of floor beams.

### 8.5 Shelf Angle Floor Systems

At the present time only a limited number of tests have been carried out on this form of construction. However, the results reported have demonstrated that by selecting suitable combinations of steel beam size and depth of concrete floor unit, fire resistance periods of ½ h, 1 h and 1½ h are possible without the need for applied, lightweight fire protection. All the tests used a sand infill to simulate the thermal characteristics of a concrete screed. In practice, a concrete screed with reinforcing mesh is normally placed across the beams and floor units which will provide some additional degree of composite and continuous action. While this effect as yet, cannot be quantified, it will always provide an improvement in the fire resistance periods so far achieved. Consequently the test assemblies constructed have examined the most pessimistic situation likely to be encountered in practice.

From the tests so far carried out, Fig. 30 illustrates the influence of design loading on the fire resistance of a typical size of shelf angle floor beam and depth of concrete unit. The fire resistance periods for other combinations have been determined using finite element analysis.

It is also worth noting that the rates of vertical deflection experienced during the latter stages of a fire test on a shelf angle floor beam, are slow (typically 2-3 mm/min) in comparison to a similar size of section evaluated as a simply supported member, exposed to fire on three sides. Therefore, while Amendment 4822 (May 1985) to BS476:Part 8:1972, was not in force at the time the tests were conducted, the criterion, L/20, for assessing stability would

have applied, thereby extending the fire resistance to times beyond those quoted.

#### 8.6 'Slim' Floor Systems

Fire tests on universal column sections used as floor beams with precast concrete units resting on the lower flanges, have demonstrated the beneficial effect of this form of construction on the fire resistance of unprotected steel. Although further evaluation of the system is required including a more detailed examination of the secondary stresses, the results so far indicate that fire resistance periods of  $\frac{1}{2}$ , 1 and  $1\frac{1}{2}$  h are possible, without the need for applied lightweight fire protection.

#### 8.7 Fire Resistance of Bare Columns

Figure 31 shows the effect of section factor on the fire resistance of bare steel columns. The data also include tests on full length unloaded sections in the column furnace as well as short 1 m lengths of section standing upright inside the floor beam furnace at the Warrington Research Centre. In plotting the curve the fire resistance is taken either as the time to the limit of stability or the limiting mean steel temperature of 550°C, for members loaded to their maximum permissible design stress. It is therefore clear from Fig. 31, that bare columns with section factors up to 55 m<sup>-1</sup> (4 sided exposure) have a fire resistance of 30 min when working at full design loading (to BS449:1969).

The test carried out on a 6 inch square solid billet is also shown in Fig. 31 which when considered in relation to the point at which the fire tests on the other sections were terminated, corroborates the curve at low values of  $H_p/A$ .

#### 8.8 Columns with Blocked in Webs

A series of tests is reported in which lightweight aerated pulverised fuel ash concrete blocks were built up into the web of column sections to leave only the outside flanges exposed to fire. By protecting the web of the section using traditional building materials and skills, a relatively low cost method is available for achieving 30 min fire resistance over a wide range of sections used as columns or stanchions.

A design guide covering this form of construction 'Fire Resistant Steel Structures - Free Standing Blockwork Filled Columns and Stanchions', has already been issued as a BRE Digest<sup>2</sup>, which also considers loading the members to the new structural steel design code BS5950:Part 1:1985.

#### 8.9 Columns and Beams in Walls

Buildings constructed with load bearing columns and beams set within the walls are commonplace. The tests reported demonstrate the potentially high levels of fire resistance available with either the exposed web left bare, or filled in with lightweight building blocks. For example, Fig. 32 illustrates the effect of design load on the fire resistance of 203 x 203 mm x 52 kg/m universal column sections used in this fashion.

In the fire tests, the exposed portions of the members attained very high temperatures, ~1000°C. Despite the low strength of steel at temperatures of this magnitude, the applied loads were still supported by the much cooler areas of the sections' profile that were protected by the blockwork. However due to the steep temperature gradients created across the sections' profile, bowing arising from differential thermal expansion occurs. Therefore, designers must be aware of the potential damaging effects of lateral movement in the structure on the integrity of the walls. This is particularly important where the height of the wall is considerably greater than that evaluated in the fire test.

#### 8.10 Elevated Temperature Anisothermal Tensile Tests

Appendix B contains data sheets on the anisothermal tensile tests carried out on samples of steel removed from the unheated portions of members evaluated in the fire test furnaces. These results have been used in conjunction with similar tests on material removed from other structural sections to provide

stress/strain curves for Grades 43A and 50B steel manufactured to BS4360:1979, see Tables 4(a) and (b). Since this work was carried out, BS4360 was revised in August 1986 and the minimum yield stress of Grade 43A structural steel was raised from 255 N/mm<sup>2</sup> to 275 N/mm<sup>2</sup>. Therefore a small increase in the stress values covering the plastic portion of the stress strain curves can be expected for the higher strength steel, and it would not be unreasonable to expect the uplift to be approximately in the proportion of 275/255.

The data presented in Tables 4(a) and (b) are based upon a steel heating rate of 10°C/min. However, there is a small dependency of strength on heating rate due to 'creep' at longer heating times and therefore at 1% total strain, the following adjustments can be made relative to 10°C/min.

20°C/min +15°C

5°C/min -15°C

2.5°C/min -25°C

$H_p$  (4) infers total perimeter

$H_p$  (3) infers total perimeter less the width of one flange

In deriving the above values  $H_p$  is in metres and A in square metres.

**TABLE 4**  
**ELEVATED TEMPERATURE STRESS/STRAIN DATA FOR BS4360:1979 STRUCTURAL STEELS**  
**DERIVED FROM ANISOTHERMAL TENSILE TESTS**

Strain %	Stress in N/mm <sup>2</sup> for Various Temperatures, °C

LS476:PART 8:1972 FURNACE HEATING CURVE

FIG. 1  
(R2/7084)

THE FLOOR BEAM FURNACE FIRE TEST FACILITY  
AT WARRINGTON RESEARCH CENTRE  
FIG. 2(a)

A 4.5 m LONG FLOOR BEAM BEING REMOVED FROM THE FURNACE  
FOLLOWING A FIRE TEST FIG. 2(b)

(080)

FIG. 3(a)  
(R2/7085)

LONGITUDINAL SECTION SHOWING THE GENERAL ARRANGEMENT  
FOR A SIMPLY SUPPORTED FLOOR BEAM TEST ASSEMBLY

VERTICAL SECTION THROUGH A FLOOR BEAM TEST ASSEMBLY

FIG. 3(b)  
(R2/7086)

VERTICAL SECTION THROUGH A STEEL BEAM  
AND REINFORCED COMPOSITE CONCRETE SLAB

FIG. 4(b)  
(R2/7088)

FIG. 5 (a)  
(R2/7089)

LONGITUDINAL SECTION SHOWING THE GENERAL ARRANGEMENT  
FOR A FLOOR BEAM WITH VARIABLE ROTATIONAL END RESTRAINT

VERTICAL SECTION THROUGH A FLOOR BEAM TEST ASSEMBLY  
WITH ROTATIONAL END RESTRAINT

FIG. 5(b)  
(R2/7090)

SECTION X-X

FIG. 5(c)  
(R2/7091)

LONGITUDINAL SECTION SHOWING THE GENERAL ARRANGEMENT FOR A FLOOR BEAM WITH CONSTANT ROTATIONAL END RESTRAINT

FIG. 6 (a)  
(R2/7092)

VERTICAL SECTION THROUGH A FLOOR BEAM TEST ASSEMBLY  
WITH ROTATIONAL END RESTRAINT

FIG. 6 (b)  
(R2/7093)

SCHMATIC ILLUSTRATION OF THE 'CRADLE' ARRANGEMENT  
USED FOR APPLYING AND MAINTAINING CONSTANT ROTATIONAL  
END RESTRAINING MOMENTS

FIG. 6(c)  
(R2/7094)

Thermal restraint frame

8.1 m

4.6 m

254 x 254 mm x 73 kg/m  
'U' column

914 x 305 mm x 224 kg/m  
'U' beam

Web  
stiffener

Furnace

Test beam

SCHEMATIC ILLUSTRATION SHOWING A PLAN VIEW OF THE THERMAL RESTRAINT FRAME SURROUNDING THE FLOOR BEAM FURNACE

FIG. 7(a)  
(R2/7095)

SCHEMATIC ILLUSTRATION SHOWING THE END CONDITIONS  
OF A FIRE TEST BEAM WITH BOTH THERMAL  
AND APPLIED ROTATIONAL END RESTRAINT

FIG. 7(b)  
 (R2/7096)

GENERAL PLAN VIEW OF A SHELF ANGLE FLOOR BEAM TEST ASSEMBLY

FIG. 8 (a)  
(R2/7097)

FIG. 8 (b)  
(R2/7098)

VERTICAL SECTION THROUGH A SHELF ANGLE FLOOR BEAM

Longitudinal Section

Transverse Section

Concrete crushing strength: 25 N/mm<sup>2</sup> at 28 days

Reinforcement: cold worked high yield bar to BS4461

Longitudinal Section

Transverse Section

Concrete crushing strength: 25 N/mm<sup>2</sup> at 28 days

Reinforcement: cold worked high yield bar to BS4461

DESIGN DETAILS OF THE REINFORCED CONCRETE FLOOR UNITS WITH TAPERED ENDS

FIG. 9(b)  
(R2/7100)

DESIGN DETAILS FOR LOADING A SHELF ANGLE FLOOR BEAM ASSEMBLY

FIG. 10  
(R2/7101)

GENERAL PLAN VIEW OF A 'SLIM' FLOOR BEAM TEST ASSEMBLY

FIG. 11(a)  
(R2/7102)

FIG. 11 (b)  
(R2/7103)

VERTICAL SECTION THROUGH A 'SLIM' FLOOR BEAM  
WITH HOLLOW CONCRETE FLOOR UNITS

Longitudinal Section

Transverse Section

130 mm diameter tubular void

Reinforcement Detail

DESIGN DETAILS OF THE 'SPIROLL' FLOOR UNITS

FIG. 12(a)  
(R2/7104)

Longitudinal Section

Transverse Section

Concrete crushing strength: 25 N/mm<sup>2</sup> at 28 days

Reinforcement: cold worked high yield bar to BS4461

DESIGN DETAILS OF THE SOLID REINFORCED CONCRETE FLOOR UNITS

FIG. 12(b)  
(R2/7105)

DESIGN DETAILS FOR LOADING A 'SLIM' FLOOR BEAM ASSEMBLY

FIG. 13  
(R2/7106)

THE COLUMN FURNACE FIRE TEST FACILITY AT FIRTO, BOREHAMWOOD  
FIG. 14 (a)

A STEEL COLUMN WITH A BLOCKED IN WEB FOLLOWING A FIRE TEST  
FIG. 14(b)

VERTICAL SECTION OF AN UNPROTECTED COLUMN TEST ASSEMBLY (UK)

FIG. 15  
(R2/7107)

VERTICAL SECTION OF AN UNPROTECTED COLUMN TEST ASSEMBLY  
 SPONSORED BY ARBED SA

FIG. 16  
 (R2/7108)

VERTICAL SECTION OF A COLUMN TEST ASSEMBLY  
WITH THE WEB PROTECTED BY LIGHTWEIGHT BLOCKWORK

FIG. 17(a)  
(R2/7109)

SECTION X-X THROUGH A STEEL COLUMN  
WITH A BLOCKED IN WEB

FIG. 17(b)  
(r2/7110)

CONFIGURATION OF A STEEL COLUMN BUILT INTO WALL

FIG. 18

FABRICATION OF THE WALL TEST ASSEMBLY  
FIG. 19(a)

THE EXPOSED WALL SURFACE  
BEFORE TESTING

NOTES

- (a) Slab size = 130 mm thick x 650 mm wide  
Slab mass per metre = 1.857 kN
- (b) Equals 88.2% of the maximum allowable bending stress to BS 449 : Part 2 : 1969 for a Grade 43A steel section
- (c) Calculation based upon deriving the required loads at two loading points only
- (d) Two loading points each located 1.5 m from supports
- (e) Initial ambient temperature = 21 deg. C
- (\*) Not measured

TEST CONDITIONS

END CONDITIONS : SIMPLY SUPPORTED  
 COVER SLAB (a) : DENSE CONCRETE, SEGMENTED  
 EFFECTIVE SPAN : 4.500 m  
 DEAD LOAD : 2.272 kN/m  
 MAXIMUM BENDING STRESS IN LOWER FLANGE : 145.5 N/mm<sup>2</sup> (b)  
 CENTRAL BENDING MOMENT : 71.970 kN.m (c)  
 CENTRAL BENDING MOMENT FROM DEAD LOAD : 5.751 kN.m  
 CENTRAL BENDING MOMENT REQUIRED FROM IMPOSED LOAD : 66.219 kN.m  
 LOADS APPLIED (d) : 44.15 kN

ALTHOUGH THIS TEST WAS CARRIED OUT FULLY IN ACCORDANCE WITH BS476: PART 8, THE RESULTS ARE SIGNIFICANTLY AT VARIANCE WITH ALL OTHER BEAM TESTS

This was possibly due to the following :-

- 1 The test beam was subject to 2 point loading (all other beam tests in this publication were loaded at 4 points)
- 2 Despite the combustion gas furnace temperature following the ISO 834 heating curve, the heating rate of the steel was uncharacteristically slow for this size of beam

NOTES

- (a) Slab size = 130 mm thick x 642 mm wide  
Slab mass per metre = 1.834 kN
- (b) Equals the maximum allowable to BS 449 : Part 2 : 1969 based on a simply supported Grade 43A beam section in which the composite action between steel and concrete is ignored
- (c) Determined from "Design Tables For Composite Steel and Concrete Beams", published by CONSTRADO, in accordance with CP 117 : Part 1 : 1965
- (d) Initial ambient temperature = 11 deg. C
- (\*) No data collected during the first 12 minutes of the test due to instrumentation malfunction

NOTES

- (a) Slab size = 130 mm thick x 635 mm wide  
Slab mass per metre = 1.814 kN
- (b) Equals the maximum allowable bending stress to BS 449 : Part 2 : 1969 for a Grade 43A steel section
- (c) Load increased to maintain a maximum working stress of 165 N/mm<sup>2</sup> at the mid-span position
- (d) Between supports
- (e) Loads reduced after 33 minutes to those for a simply supported beam with a maximum bending stress of 165 N/mm<sup>2</sup> at the mid-span position. Had the test continued with the original applied loads held constant, it is estimated that failure would have occurred after 37.5 minutes
- (f) Initial ambient temperature = 11 deg. C

WEB	298	484	23.5

NOTES

- (a) Slab size = 130 mm thick x 630 mm wide  
Slab mass per metre = 1.800 kN
- (b) Calculated for a simply supported beam subject to a maximum bending stress of 165 N/mm<sup>2</sup> in the lower flange
- (c) Between supports
- (d) Applied at a distance of 0.715 m from each support
- (e) Initial ambient temperature = 5 deg. C
- (f) After 22 minutes the applied end loads were allowed to increase naturally and reached an average value of 90.56 kN (equivalent to 81.5% rotational end restraint) after 40 minutes, at which time the beam had attained a deflection of approximately L/30. The test was extended from 40 to 45 minutes with increased applied end loads of 96.067 kN (equivalent to 86.4% rotational end restraint)

NOTES

- (a) For elevated temperature anisothermal tensile properties see Data Sheet No. 86
- (b) Slab size = 135 mm thick x 645 mm wide  
Slab mass per metre = 1.913 kN
- (c) Calculated for a simply supported beam subject to a maximum bending stress of 165 N/mm<sup>2</sup> in the lower flange
- (d) Between supports
- (e) Actual end restraining moments = 100.5% of central bending moment
- (f) Applied at a distance of 0.715 m from each support
- (g) Initial ambient temperature = 10 deg. C
- (\*) No data collected at these times due to instrumentation malfunction

NOTES

- (a) For elevated temperature anisothermal tensile properties see Data Sheet No. 87
- (b) Slab size = 130 mm thick x 690 mm wide  
Slab mass per metre = 1.971 kN
- (c) Calculated for a simply supported beam subject to a maximum bending stress of 165 N/mm<sup>2</sup> in the lower flange
- (d) Between supports
- (e) Actual end restraining moments = 69.1% of central bending moments
- (f) Applied at a distance of 0.715 m from each support
- (g) Initial ambient temperature = 6 deg. C

NOTES

- (a) Slab size = 130 mm thick x 630 mm wide  
Slab mass per metre = 1.800 kN
- (b) Calculated for a simply supported beam subject to a maximum bending stress of 165 N/mm<sup>2</sup> in the lower flange
- (c) Between supports
- (d) Applied at a distance of 0.715 m from each support
- (e) Initial ambient temperature = 14 deg. C
- (f) Rotational end restraint increased to 43% during the test due to movement in the thermal restraining frame

FLANGE	287	478	34.0

NOTES

- (a) Based upon nominal dimensions and properties
- (b) Assuming a maximum bending stress of 165 N/mm<sup>2</sup> in the lower flange
- (c) Estimated load taking into account local bending and shear stresses
- (d) Applied 0.5m from the centre line of the column
- (e) Equivalent to 121.3% of the maximum permissible load according to BS 449 : Part 2 : 1969
- (f) Equivalent to 108.1% of the maximum permissible load according to BS 449 : Part 2 : 1969
- (g) Amendment No. 4822 (May 1985) incorporated into BS 476 : Part 8 : 1972 for determination of fire resistance
- (h) The limiting rate of deflection, (R), was exceeded before a deflection of L/30 was achieved. Therefore stability is assessed on the time taken to achieve L/30
- (i) Initial ambient temperature = 22 deg. C
- (\*) Not measured

TEST CONDITIONS

END CONDITIONS	: SIMPLY SUPPORTED
EFFECTIVE SPAN	: 4.500 m
CONCRETE FLOOR UNITS	: HOLLOW, 200 mm DEEP "SPIROLL"
SAFE WORKING LOAD	: 262.5 kN (a)(b)
OPERATING LOAD REQUIRED	: 262.5 kN
DEAD LOAD (BEAM + SAND)	: ~ 5.5 kN
TOTAL FORCE REQUIRED	: 257 kN
DEAD LOAD (CONCRETE + LOAD SPREADERS)	: ~43.6 kN
REACTION ON EACH FLANGE	: 10.9 kN
IMPOSED FORCE REQUIRED	: 117.6 kN (PER FLANGE) (c)(d)
LOADS APPLIED	: 41.08 kN (BY EACH JACK)
COMBINED STRESS ON LOWER FLANGE - U.D.L.	: 200.1 N/mm <sup>2</sup> (e)
COMBINED STRESS ON LOWER FLANGE - POINT LOADING	: 178.4 N/mm <sup>2</sup> (f)

FLANGE	285	492	25.5
WEB	287	472	28.0

TEST CONDITIONS

HEIGHT OF COLUMNS	: 300	cm
EFFECTIVE LENGTH	: 255	cm
RADIUS OF GYRATION (x-x)	: 8.90	cm
RADIUS OF GYRATION (y-y)	: 5.16	cm
SLENDERNESS RATIO (x-x)	: 28.65	
MAXIMUM AXIAL STRESS	: 143.5	N/mm <sup>2</sup>
AREA OF CROSS SECTION	: 66.4	cm <sup>2</sup>
MAXIMUM LOAD PER COLUMN	: 953	kN
LOAD APPLIED PER COLUMN	: 476.5	kN (b)(c)

NOTES

- (a) For elevated temperature anisothermal tensile properties see Data Sheet No. 88
- (b) Equals 50% of the maximum permissible load according to BS 449 : Part 2 : 1969
- (c) Examination of the test behaviour by the British Steel Corporation suggests that for the x-x axis the effective length factor = 1.0 - 1.2 (estimate) and for the y-y axis the effective length factor = 1.0  
 Effective length (x-x) = 300 - 360 cm  
 Effective length (y-y) = 300 cm  
 Slenderness ratio (x-x) = 33.71 - 40.45  
 Slenderness ratio (y-y) = 58.14  
 Hence the y-y axis governs collapse and the maximum allowable axial stress on the gross section = 127 N/mm<sup>2</sup>  
 Maximum permissible load per column = 843.3 kN  
 Therefore the load applied per column (476.5 kN) equals 56.5% of the maximum permissible load according to BS 449 : Part 2 : 1969
- (d) Initial ambient temperature = 19 deg. C
- (e) Accurate to the nearest 0.5 mm
- (\*) Not measured

NOTES

- (a) An effective length factor of 0.7 has been assumed
- (b) Examination of the test behaviour by the British Steel Corporation suggests that for the x-x axis the effective length factor = 1.0 - 1.2 (estimate) and for the y-y axis the effective length factor = 1.0. The height of the columns should also be taken as 300 cm.  
 Effective length (x-x) = 300 - 360 cm  
 Effective length (y-y) = 300 cm  
 Slenderness ratio (x-x) = 33.71 - 40.45  
 Slenderness ratio (y-y) = 58.14  
 Hence the y-y axis governs collapse and the maximum allowable axial stress on the gross section = 127 N/mm<sup>2</sup>  
 Maximum permissible load per column = 843.3 kN  
 Therefore the load applied per column (969.5 kN) equals 115% of the maximum permissible load according to BS 449 : Part 2 : 1969
- (c) 80% of 31 minutes
- (d) Initial ambient temperature = 13 deg. C
- (\*) Not measured

ROOM TEMPERATURE TENSILE PROPERTIES

POSITION	LYS	TS	ELONG
	N/mm <sup>2</sup>	N/mm <sup>2</sup>	%
FLANGE	292	489	31.5

NOTES

- (a) Oven dry density
- (b) The y-y axis therefore governs collapse
- (c) Equals 40% of the maximum permissible load according to BS 449 : Part 2 : 1969
- (d) Initial ambient temperature = 13 deg. C
- (\*) Not measured

TEST CONDITIONS

DENSITY OF BLOCKWORK	: 621	kg/m <sup>3</sup>	(a)
HEIGHT OF COLUMNS	: 300	cm	
EFFECTIVE LENGTH (x-x)	: 300-360cm	(estimate)	
EFFECTIVE LENGTH (y-y)	: 300	cm	
RADIUS OF GYRATION (x-x)	: 8.90	cm	
RADIUS OF GYRATION (y-y)	: 5.16	cm	
SLENDERNESS RATIO (x-x)	: 33.71 - 40.45		
SLENDERNESS RATIO (y-y)	: 58.14		(b)
MAXIMUM AXIAL STRESS	: 127	N/mm <sup>2</sup>	
AREA OF CROSS SECTION	: 66.4	cm <sup>2</sup>	
MAXIMUM LOAD PER COLUMN	: 843.3	kN	
LOAD APPLIED PER COLUMN	: 337	kN	(c)

- NOTES:- (a) Initial ambient temperature = 22 deg. C  
 (b) Standard 'TEMBO' pre-stressed hollow concrete units supplied by Richard Lees Ltd. were used. Their dimensions were:- Length 1550 mm, Width 590 mm, Thickness 155 mm. The ends were solid with a 50 mm deep x 100 mm wide rebate. The angles were bolted to the web of the beam section so as to leave a clearance gap of 160 mm between the angle and the underside of the upper flange of the beam. Sand was used to cover the upper flange and also to fill the gap between the ends of the concrete units and the web of the beam.
